

DockFlow

Clothing Warehouse & Delivery Management System

A website that brings stock, orders and delivery updates together.

What our project title means

PROJECT TITLE

DockFlow

Clothing Warehouse & Delivery
Management System

A website for managing a clothing warehouse and its deliveries.

Dock

The warehouse: men's, women's and kids' clothes stored by size, color and location.

Flow

Stock, orders and delivery updates moving together through one system.

Management System

A website where staff add stock, create orders and update deliveries.

PROBLEM STATEMENT

Clothing warehouses often keep stock, orders and delivery updates in separate places. Stock counts drift, orders slow down and shipments are hard to follow. DockFlow brings all three together in one website.

Objectives and scope

1

Track men's, women's and kids' clothes by size, color and location.

2

Let staff add stock and create orders from one website.

3

Record delivery updates and keep them easy to follow.

4

Use the right database for each job: MySQL, MongoDB and Kafka.

WHAT STAFF CAN DO

Add stock

Create orders

Update deliveries

CLOTHING CATEGORIES

Men's

Women's

Kids'

Tracked by size, color and location

System architecture

Is DockFlow feasible? Yes, on four counts

Technical

FEASIBLE

- MySQL, MongoDB and Kafka are established, open-source tools
- Each tool has a clear job in the design

Operational

FEASIBLE

- One simple website for staff
- Add stock, create orders, update deliveries

Economic

FEASIBLE

- Open-source stack, no paid integrations
- Payments and courier GPS are out of scope

Schedule & scope

FEASIBLE

- Core flow is already a working course project
- Extras are kept as future improvements

Current status, limits and risks

Built now

- Clothes tracked by size, color and location
- Add stock and create orders (MySQL)
- Flexible delivery updates (MongoDB)
- Shipment events passed with Kafka

Not connected

- Real courier GPS
- Payments

Future work

- CI/CD
- Full C4 diagrams

Risk	How DockFlow handles it
Three tools add setup effort	Each tool has one narrow job: MySQL for stock and orders, MongoDB for delivery updates, Kafka for shipment events.
No real courier GPS	Delivery status is updated by staff on the website; GPS is a planned extension.
Project is not yet production-ready	Scoped as a working course project; CI/CD and C4 diagrams are listed as future improvements.

The real-world need behind DockFlow

WHAT GOES WRONG TODAY

Inaccurate stock records

Customers may get wrong or missing clothes.

Delayed orders

Slow orders mean long waits for deliveries.

Unclear delivery status

Staff and customers cannot see where a shipment is.

Disconnected tools

Staff lose time moving between separate records.

WHO BENEFITS FROM DOCKFLOW

Warehouse staff

One place for stock, orders and deliveries

Clothing businesses

Accurate stock and smoother order handling

Customers: men, women, kids

Right clothes, delivered with clear status

Delivery partners

Clear shipment updates passed between services

Social impact and SDG alignment

9

SDG

Industry, Innovation & Infrastructure

Modern, database-driven tools for a small logistics operation.

12

SDG

Responsible Consumption & Production

Accurate stock records reduce wrong, lost or surplus items.

8

SDG

Decent Work & Economic Growth

Less manual re-entry lets staff spend time on real work.

SOCIETAL OUTCOME

Fewer errors and delays between the warehouse and the customer, and clearer delivery updates for everyone involved.

DockFlow compared with existing approaches

Aspect	Manual records and spreadsheets	Typical single-database system	DockFlow
Stock tracking	Counts drift from real stock	Tracks stock in one database	By size, color and location for men's, women's and kids' clothes
	Separate sheets, manual re-entry	Orders in the same database	Orders created against tracked stock in MySQL
	Phone calls and notes	Fixed table columns	Flexible updates stored in MongoDB
	None	Direct calls between modules	Shipment events passed through Kafka
	No database	One database for everything	A different tool for each job

What is new in DockFlow

Right database for each job

MySQL keeps stock and orders consistent.
MongoDB stores delivery updates flexibly.

Event-driven shipments

Kafka passes shipment events between
services as they happen.

One place for everything

Stock, orders and delivery updates come
together in a single website.

HOW ONE DELIVERY MOVES THROUGH DOCKFLOW

Summary: DockFlow against the criteria

Clear title

Clothing warehouse and delivery management website with defined objectives.

Feasible

Open-source stack, working core flow, known limits and risks.

Societal need

Helps staff, businesses, customers and delivery partners; fits SDGs 9, 12 and 8.

Novel

MySQL, MongoDB and Kafka, each used for its own job.

Thank you

We are happy to take your questions.
